(57) **ABSTRACT**

Embodiments herein relate to a method in a mobile terminal (10) for requesting access to a wireless communication system. The mobile terminal (10) receives broadcasted system information directly indicating first access request preambles for a first contention based channel, and indirectly indicating second access request preambles for a second contention based channel based on the directly indicated first access request preambles. The mobile terminal (10) further derives the second access request preambles from the first access request preambles. Additionally, the mobile terminal requests access using the second access request preambles or the first access request preambles to access the wireless communication system.

# MOBILE TERMINAL, BASE STATION AND METHODS THEREIN

## TECHNICAL FIELD

Embodiments herein relate to a mobile terminal, a base station and methods therein. In particular, embodiments herein relate to manage access to a first contention based channel and a second contention based channel.

## BACKGROUND

In today's wireless communication systems a number of different technologies are used, such as Long Term Evolution (LTE), LTE-Advanced, Wideband Code Division Multiple Access (WCDMA), Global System for Mobile communications/Enhanced Data rate for GSM Evolution (GSM/EDGE), Worldwide Interoperability for Microwave Access (WiMax), or Ultra Mobile Broadband (UMB), just to mention a few possible implementations. A wireless communication system comprises base stations providing radio coverage over at least one respective geographical area forming a cell. The cell definition may also incorporate frequency bands used for transmissions, which means that two different cells may cover the same geographical area but using different frequency bands. Mobile terminals are served in the cells by the respective base station and are communicating with respective base station. The mobile terminals transmit data over an air or radio interface to the base stations in uplink (UL) transmissions and the base stations transmit data over an air or radio interface to the mobile terminals in downlink (DL) transmissions.

Release 6 of the third generation partnership project (3GPP) standards introduced Enhanced Uplink (E-UL), also known as High Speed Uplink Packet Access (HSUPA). Compared to previous releases E-UL improved performance of uplink communications—those from a mobile terminal, i.e., User Equipment, UE, to a base station—using higher data rates, reduced latency, and improved system capacity. These enhancements were implemented through a new transport channel called the Enhanced Dedicated Channel (E-DCH). In Release 6, and continuing into Release 7, however, a mobile terminal may only use the E-DCH in limited circumstances.

Specifically, at the Radio Resource Control (RRC) level, a mobile terminal may be in two basic operation modes, called IDLE mode and CONNECTED mode. In IDLE mode, the mobile terminal requests an RRC connection before sending any uplink data or responding to a page. In CONNECTED mode, by contrast the mobile terminal has an RRC connection, and may be in one of several service states: Universal Mobile Telecommunications System (UMTS) Radio Access Paging Channel (URA\_PCH) state, a Cell Paging Channel (CELL\_PCH) state, a Cell Forward Access Channel (CELL\_FACH) state, and Cell Dedicated Channel (CELL\_DCH) state. The URA\_PCH and CELL\_PCH states are paging states in which the mobile terminal sleeps and only occasionally wakes up to check for a page. To send uplink data, the mobile terminal must be moved to the CELL\_FACH or CELL\_DCH state. When moved to the CELL\_FACH state in Releases 6 and 7, the mobile terminal may send a relatively small amount of uplink data over a contention-based transport channel called the Random Access Channel (RACH), but not over the E-DCH; to send data over the E-DCH, the mobile terminal had to be moved to the CELL\_DCH state, which introduces a delay.

To reduce the delay caused by the state transition, Release 8 of the 3GPP standards allocates a portion of E-DCH

2

resources as common resources, also called common E-DCH resources, that may be used on a contention-basis by mobile terminals in the CELL\_FACH state. Accordingly, mobile terminals in the CELL\_FACH state with a relatively large amount of uplink data may send that data over the E-DCH using the common E-DCH resources rather than having to make multiple accesses over the RACH or switch to the CELL\_DCH state.

This however comes at a cost of increased downlink control signaling. Indeed, the base station now broadcasts system information to mobile terminals that informs them about which access request preambles may be used for requesting E-DCH access, and which E-DCH resources are available as common E-DCH resources. Among other disadvantages, this increased DL control signaling may delay the base station's signaling of more crucial system information.

For example, a base station often broadcasts system information in a series of so-called System Information Blocks (SIBs). Different types of system information are broadcasted in different types of SIBs, one after another in a time division manner. This process is repeated to continually provide system information to mobile terminals on an as-needed basis. Accordingly, any given large SIB delays broadcast of the entire series of SIBs, which in turn increases the time between which any given SIB is repeated, i.e., the SIB's repetition factor. If the SIB's repetition factor is excessively large for an SIB with crucial system information, there may be long periods of time in which a mobile terminal cannot be paged, send uplink data, perform a cell update, or perform a fallback to a circuit-switched network, also called CS fallback. This type of delays may be caused by the DL control signaling associated with Release 8 of the 3GPP standards resulting in a reduced performance of the wireless communication system.

## SUMMARY

An object of embodiments herein is to enhance the performance of the wireless communication system.

According to some embodiments, the object is achieved by a method in a base station for managing access to a first contention based channel and a second contention based channel. The base station encodes system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the directly indicated first access request preambles. The base station further broadcasts the encoded system information to mobile terminals.

According to some embodiments, the object is yet achieved by a base station for managing access to the first contention based channel and the second contention based channel. The base station comprises a processing circuit configured to encode system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the directly indicated first access request preambles. The base station further comprises a transmitter circuit configured to broadcast the encoded system information to mobile terminals.

According to some embodiments, the object is achieved by a method in a mobile terminal for requesting access to the wireless communication system. The mobile terminal receives broadcasted system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the

directly indicated first access request preambles. The mobile terminal further derives the second access request preambles from the first access request preambles. Additionally, the mobile terminal requests access using the second access request preambles or the first access request preambles to access the wireless communication system.

According to some embodiments, the object is additionally achieved by a mobile terminal for requesting access to a wireless communication system. The mobile terminal comprises a receiver circuit configured to receive broadcasted system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the directly indicated first access request preambles. The mobile terminal further comprises a processing circuit configured to derive the second access request preambles from the first access request preambles. The processing circuit is further configured to request access using the second access request preambles or the first access request preambles to access the wireless communication system.

By indicating the second access request preambles based on e.g. as a function of the directly indicated first access request preambles, the amount of data signalled in the system information is reduced. Thus, the delay for transmitting system information is reduced and the performance of the wireless communication system is improved.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments will now be described in more detail in relation to the enclosed drawings, in which:

FIG. 1 is a schematic block diagram depicting a wireless communication system,

FIG. 2 is a combined flowchart and signalling scheme depicting embodiments herein,

FIG. 3 is a schematic flowchart depicting embodiments of a method in a base station,

FIG. 4 is a block diagram depicting embodiments of a base station,

FIG. 5 is a schematic flowchart depicting embodiments of a method in a mobile equipment, and

FIG. 6 is a block diagram depicting embodiments of a mobile equipment.

#### DETAILED DESCRIPTION

FIG. 1 is a schematic overview depicting a wireless communication system, also referred to as a radio communications network. In today's wireless communication systems a number of different technologies are used, such as LTE, LTE-Advanced, WCDMA, GSM/EDGE, WiMax, or UMB, just to mention a few possible implementations. The wireless communication system, which includes a base station 12 and one or more other entities 14. The base station 12 provides an uplink communications channel 16 for receiving uplink data from individual mobile terminals 10, 10-1, 10-2 . . . 10-N in a group 20 of N mobile terminals, also conveniently referred to as "users" or "user equipments". The base station 12 further provides a downlink communications channel 22 for sending transmissions to mobile terminals 10-10-N in the group 20, including control signaling.

It should be understood by the skilled in the art that "mobile terminal" is a non-limiting term which means any user equipment, wireless terminal, device or node e.g. Personal Digital

Assistant (PDA), laptop, mobile, sensor, relay, mobile tablets or even a small base station communicating within a cell served by the base station 12.

The base station 12 may also be referred to as e.g. a NodeB, an evolved Node B (eNB, eNode B), a radio base station, a base transceiver station, Access Point Base Station, base station router, a base station controller, a radio network controller, or any other network unit capable to communicate with the mobile terminal 10 within the cell served by the base station 12 depending e.g. of the radio access technology and terminology used.

The base station 12 supports two different Contention-Based (CB) channels of the uplink communications channel 16, one legacy CB channel, e.g., offering low data rates such as a RACH, and one non-legacy CB channel, e.g., offering high data rates such as a E-DCH. Some mobile terminals 10-1-10-N, referred to as legacy mobile terminals, only support the legacy CB channel, while others support both CB channels. If the mobile terminal 10 supports both channels, the mobile terminal 10 may preferentially select the non-legacy CB channel for sending uplink data. In order to manage access to both CB channels, the base station 12 broadcasts system information for both CB channels on a control channel of the downlink communications channel 22. Contention based channel means herein a channel that many mobile terminals may use without pre-coordination. Thus, for a contention based channel the base station 12 broadcasts access request preambles that the mobile terminal 10 randomly selects. In a non-contention based channel the base station 12 first maps a access request preamble to the mobile terminal 10 and then transmits the mapped access request preamble to the mobile terminal 10 for the mobile terminal 10 to use. In particular, the base station 12 broadcasts over the control channel system information that indicates which first access request preambles and second access request preambles may be used for requesting access using respective ones of the CB channels. Each access request preamble may be mapped to a particular resource of a CB channel. In this regard, the CB channels share the access request preamble "space." The base station 12 may also broadcast system information that indicates which resources of the CB channels are available.

As a point of advantage, the base station 12 intelligently broadcasts system information for the CB channels, in order to limit the amount of downlink control signaling. According to embodiments herein, instead of broadcasting system information to mobile terminals 10-10-N that independently indicates access request preambles for respective ones of the CB channels, the base station 12 broadcasts system information indirectly indicating the access request preambles for one channel, e.g., the non-legacy CB channel, based on, e.g. as a function of the access request preambles for the other channel, e.g., the legacy CB channel. Correspondingly, the mobile terminal 10 receives system information directly indicating the access request preambles for one channel, e.g., the legacy CB channel, and derives the access request preambles for the other channel, e.g., the non-legacy CB channel, as a function of the directly indicated access request preambles. In some embodiments, the mobile terminal 10 then randomly selects one of the derived access request preambles and transmits the selected access request preamble to the base station 12, in order to request access to the associated CB channel, that is, the non-legacy channel or the legacy channel. It should be understood that the system information may directly indicate the access request preambles of the non-legacy channel and indirectly indicate the request preambles of the legacy channel.

5

Embodiments described herein may advantageously reduce the signaling required in System Information Blocks (SIB) to broadcast the total amount of common E-DCH resources around 70% compared with the current signaling. In particular, after Release 8 (Rel-8), SIB type 5 (SIB5), which is the SIB type that indicates the preambles may be substantially enlarged due to the common E-DCH configurations. A total of 32 common E-DCH resources may be configured in a cell. If all these resources are included in SIB5, the size of SIB5 would be increased by 8 segments, where a segment comprises a header and a data field, e.g. the data field carries the encoded system information elements. This would mean that SIB5 may take more than 12 segments, and would in turn mean that a Master Information Block up to 16 segments, SIB type 11 (SIB11) up to 16 segments, and SIB5 would take more than 50% of the 64 segments available in a 1.280 second scheduling window frame. As a consequence, SIB5 will not be able to be broadcasted in less than 640 ms, meaning that the repetition factor may need to be augmented. However, according to embodiments herein, the number of segments to broadcast SIB5 may be reduced to less than 3 segments. This means that the repetition factor of the SIB5 may be reduced. Hence, the delay to transmit the URA/CELL updates Radio Bearer (RB) reconfiguration when it applies, or the delay introduced in the CS fall back mechanism will be minimized. In more detail, SIBs are read by the mobile terminal 10 in different stages. For example, when the mobile terminal 10 is switched on, or when the mobile terminal 10 moves from CELL\_DCH state to CELL\_FACH state, the mobile terminal 10 needs to acquire the SIBs again. Similarly, when the mobile terminal 10 moves to another cell, the new SIBs have to be read.

Cell update will be the most impacted procedure. Cell update is done when moving from CELL\_DCH state to CELL\_FACH state if the IDs are not included or the mobile terminal 10 selects a different cell than the one indicated in the RB reconfiguration. Cell Update is also performed when the mobile terminal 10 changes the cell. For E-DCH in mobile terminals in CELL\_FACH state and CELL\_DCH state, the Cell Update is also required after a Radio Link (RL) failure. There are other cases in which a cell update is required.

Furthermore, in Release-10 of the 3GPP standards, also known as 4<sup>th</sup> Generation, CS fallback from LTE was introduced. This feature may require the mobile terminal 10 to read the SIBs before starting the procedure.

Those skilled in the art will appreciate that while the above examples have been described in the context of 3GPP standards, these teachings are applicable to a wide range of system types, communication channelization schemes, etc.

FIG. 2 is a schematic combined flowchart and signaling scheme depicting some embodiments herein.

Step 201. The base station 12 encodes the system information to be broadcasted to mobile terminals within an area covered by the base station 12. The system information is encoded so that first access request preambles for the first contention based channel are directly indicated. The second access request preambles for the second contention based channel is indirectly indicated by being indicated based on the indicated first access request preambles. Indirectly herein means that the second access request preambles are derivable from the first access request preambles, e.g. as a function of the indicated first access request preambles. For example, access request preambles of a common E-DCH are indicated as an inverse of access request preambles, e.g. logical negotiation of each bit, of a Physical Random Access Channel

6

(PRACH) or indicated as being not the access request preambles of PRACH. The encoding may comprise physical layer encoding.

Step 202. The encoded system information is broadcasted to the mobile terminal 10.

Step 203. The mobile terminal 10 that has received the broadcasted system information that directly indicates the first access request preambles for the first contention based channel, derives the second access request preambles for the second contention based channel as a function of the directly indicated first access request preambles.

As a specific example in the context of 3GPP specifications, the base station 12 may support CB channels that correspond to the Random Access Channel (RACH) and the common Enhanced Dedicated Channel (E DCH). Accordingly, the base station 12 broadcasts system information for these channels in a System Information Block (SIB), namely SIB Type 5. System information for the RACH is broadcast in SIB5 using the Information Element (IE) "PRACH System Information List," while system information for the common E-DCH is broadcast in SIB5 using the IE "Common E-DCH System Information." An access request preamble to be used corresponds to a PRACH preamble, which is characterized by a signature sequence, also referred to as signature, a scrambling code, and a sub-channel.

In some embodiments, the base station 12 may in step 202 also reduce downlink control signaling by broadcasting system information that intelligently indicates available resources of a CB channel. In particular, processing circuits of the base station 12 may encode in step 203 system information that indicates available resources of a CB channel relative to other available resources of that channel, e.g., relative to the position in which other available resources are indicated in the system information, rather than indicating each resource independently. In some embodiments, for example, the available resources are indicated in an ordered list, and the base station 12 indicates available resources as a function of their position in the list relative to other resources. The TX circuits of the base station 12 broadcast this system information in a manner similar to that described above with respect to the information about the access request preambles.

Correspondingly, the RX circuits of the mobile terminal 10 in various embodiments are configured to receive system information that indicates a first available resource of a CB channel. The processing circuits of the mobile terminal 10 are configured to then derive information for a second available resource of the CB channel based on e.g. as a function of the first available resource. This may entail, for instance, deriving information for the second available resource according to a pre-determined rule that defines the second resource as a function of the first resource, e.g., as a function of the first resource's position within an ordered list describing the resources. In various embodiments, the second available resource of the CB channel is mapped to an access request preamble randomly selected by the mobile terminal. In such embodiments, the processing circuits are configured to derive information for the second available resource responsive to receiving a positive acknowledgement corresponding to the selected preamble, and to then transmit uplink data on the CB channel using the second available resource. It should be noted that the same applies for a third resource, a fourth resource and so on.

Step 204. At some point after receiving this system information, the mobile terminal 10 requests access to a supported, or preferred, one of the CB channels, the first or the second contention based channel, by randomly selecting one of the

first or second access request preambles associated with that channel, and by transmitting the selected preamble to the base station **12**.

Step **205**. The base station **12** that has received the transmitted access request preamble, performs contention management for the associated CB channel.

Step **206**. The base station **12** transmits or signals on the downlink communications channel **22** whether or not the base station **12** acknowledges or denies the mobile terminal's request for access to that channel.

Step **207**. If the mobile terminal **10** receives a positive acknowledgement, the mobile terminal **10** proceeds by sending uplink data on whichever available resource of the associated CB channel is mapped to the selected and acknowledged access request preamble.

FIG. 3 is a schematic flowchart depicting embodiments of a method in the base station **12** for managing access to the first contention based channel and the second contention based channel.

Step **301**. The base station **12** encodes system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the directly indicated first access request preambles. In some embodiments the second access request preambles are derivable as a function of the first access request preambles.

With the examples, variations, and modifications described above, those skilled in the art will also appreciate that the base station **12** herein is generally configured to perform the method illustrated in FIG. 3. In FIG. 3, processing at the base station **12** includes encoding system information that directly indicates access request preambles for one contention-based uplink channel and that indirectly indicates access request preambles for another contention-based uplink channel based on e.g. as a function of the directly indicated preambles. In some embodiments the first contention based channel corresponds to a random access channel, RACH. In some embodiments the second contention based channel corresponds to a common Enhanced Dedicated Channel, E-DCH. In some embodiments the encoded system information is comprised in a System Information Block type 5, SIB5.

In more detail, embodiments herein reduce the number of segments used in SIB5 to broadcast the IE "Common E-DCH System Info" which defines the common E-DCH resource parameters. For this purpose, a new coding is proposed for the IEs included in the IE "Common E-DCH System Info" within SIB5. The IE "Common E-DCH System Info" is an optional IE included in SIB5. The table below presents the current encoding for FDD for the IE "Common E-DCH System Info" as captured in 3GPP Technical Specification (TS) 25.331 section 10 version 10.0.0.

45

MP means Mandatory Present and OP stands for Optional. An IE which is Mandatory Present always needs to be included and have a value while the value of an optional IE may be or not be present. MD stands for Mandatory Default. When an IE is set as Mandatory Default, a value for that IE is always needed, and a particular default value is mentioned.

Embodiments herein propose modifications to some of these IEs, as described in detailed below.

In some embodiments the first access request preambles correspond to Physical Random Access Channel, PRACH, preambles characterised by a signature sequence, a scrambling code, and a sub-channel. Thus, the first access request preambles may correspond to PRACH preambles for RACH and the second access request preambles may correspond to PRACH preambles for E-UL or E-DCH preambles.

Modified IEs are:

>>>PRACH preamble control parameters for Enhanced Uplink

The PRACH preamble control parameters for E-UL IE may comprise available signatures, preamble scrambling code numbers, and Available Sub Channel Numbers.

Available Signatures

This is a bit string IE and each bit indicates whether a signature is used or not used. The signatures configured for RACH and included in the IE "Available Signatures" present in the IE "PRACH info (for RACH)". These signatures cannot be used for Enhanced Uplink in CELL\_FACH and Idle Mode. The IE "PRACH info (for RACH)" is included in the IE "PRACH System Information list" which is carried in SIB5. "PRACH System Information list", "PRACH info (for RACH)" and "Available Signatures" are mandatory present IE. Hence, they will always be included in SIB5. Thus, in some embodiments the first access request preambles are indicated in an information element denoted as Physical Random Access Channel, PRACH, info comprised in a PRACH system information list carried in System Information Block type 5, SIB5.

The IE "Available Signatures" comprised in the IE "PRACH preamble control parameters for Enhanced Uplink" is also a mandatory present value; however, in embodiments herein this IE is optional and takes a

## 11

default value. This default value may be the same or a function of another IE, e.g., the "Available Signatures" present in the IE "PRACH info (for RACH)".

As an example, the default value in various embodiments is a "NOT" or "INVERSE" function operation of the bit string values included in "Available Signatures" present in the IE "PRACH info (for RACH)".

An illustrative example is presented to clarify the concept. If the value of the IE "Available Signatures" included in the IE "PRACH info (for RACH)" is: 1111111100000000, then the default value of the IE "Available Signatures" contained in the IE "Common E-DCH System Info" would be the inverse bit operation of (1111111100000000) which is equal to 0000000011111111.

Therefore, the IE "available signatures" is set to mandatory default (MD) and the semantics of the description would say that the default value is the inverse bit-string indicated in the IE "Available Signature" in the IE "PRACH Info (for RACH)". In other words, the available signatures for Enhanced Uplink in CELL\_FACH are those signatures which are not used for RACH, unless the IE is present. Doing so, the base station 12 suppresses including this IE in the IE "PRACH preamble control parameters for Enhanced Uplink" and thereby reduces downlink control signaling. A mobile terminal 10 that does not receive such an IE nevertheless sets the IE to a default value described above. If the IE is present, the signaled values overwrite the default value. Thus, in some embodiments the first access request preambles for the first contention based channel are indicated as available signatures in the information element PRACH info and the second access request preambles for the second contention based channel are indirectly indicated as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink.

Preamble Scrambling Code Number

This IE is also included in the IE "PRACH info (for RACH)". Embodiments herein teach that the scrambling code for the common E-DCH be the same as that of the RACH, at least by default. If it would be different, the new Preamble scrambling code number in various embodiments is a function of the Preamble scrambling code number present in the IE "PRACH info (for RACH)". Hence, this IE in some embodiments is MD and by default equal to the IE "Preamble scrambling code number" indicated in the IE "PRACH info (for RACH)," and is otherwise a function of the IE "Preamble scrambling code number" indicated in the IE "PRACH info (for RACH)".

As in the previous case, the base station 12 refrains from including this IE in the IE "PRACH preamble control parameters for Enhanced Uplink" and thereby reduces downlink control signaling. A mobile terminal 10 that does not receive such an IE nevertheless sets the IE to a default value described above. If the IE is present, the signaled values overwrite the default value. Thus, in some embodiments a preamble scrambling code number of the second access request preambles is a preamble scrambling code of the first access request preambles. Alternatively, the preamble scrambling code number of the second access request preambles may be a function of the preamble scrambling code of the first access request preambles.

## 12

Available Sub Channel Number

This IE is a bit string. Each bit indicates availability for a sub channel, where the sub channels are numbered from "sub channel 0" to "sub channel 11". The value 1 of a bit indicates that the corresponding sub channel is available and the value 0 indicates that it is not available.

This IE is also included in the IE "PRACH info (for RACH)". This IE in some embodiments is also set to MD. The mandatory default value is a function of the IE "PRACH info (for RACH)".

For example, this IE may be set equal to the IE "Available Sub Channel Number" indicated in the IE "PRACH info (for RACH)". In another approach, the default value may be the INVERSE (or NOT) function of the IE Available Sub Channel Number" indicated in the IE "PRACH info (for RACH)"

As in the previous case, the base station 12 refrains from including this IE in the IE "PRACH preamble control parameters for Enhanced Uplink" and thereby reduces downlink control signaling. A mobile terminal 10 that does not receive such an IE nevertheless sets the IE to a default value described above. If the IE is present, the signaled values overwrite the default. Thus, in some embodiments an available sub channel number of the second access request preambles is set to be equal, the inverse or a 'not'-function of an available sub channel number indicated in the information element denoted PRACH info.

In some embodiments, the base station 12 also reduces downlink control signaling by intelligently broadcasting system information that indicates available resources of a CB channel, e.g., the non-legacy CB channel.

Consider a specific example in 3GPP specifications, whereby available resources comprise a combination of a power control command channel time slot, a power control command channel coding, and the like, with each component of an available resource being indicated relative to a corresponding component of another available resource.

In some embodiments the base station 12 encodes system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel. The second available resource may in some embodiments be indicated in an ordered list of resources as a function of a position of the first available resource in the ordered list.

The ordered list may in some embodiments define common Enhanced-Dedicated Channel (E-DCH) resources. Each E-DCH Resource may be defined by an Soffset information element, an Fractional Dedicated Physical Control Channel (F-DPCH) code number information element, and an E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel (E-HICH) info for common E-DCH information element.

>>Common E-DCH Resource Configuration Information List

This IE is a list which comprises all the defined common E-DCH resources. A maximum of 32 common E-DCH resources may be included in this list. For each defined common E-DCH resource, the following IEs are defined:

>>>Soffset

This IE is a MP IE which value ranges between 0 and 9. This value indicates the concrete slot within the F-DPCH in which the power control commands are included for a concrete F-DPCH code.

Instead of being MP, this IE in various embodiments is set as MD. If the IE is not present, "Soffset" takes a default

## 13

value. The default value is a function of the position of the common E-DCH resource within the list, a function the "Soffset" value of a previous common E-DCH resource instance, or a function of the position of the common E-DCH resource and the "Soffset" value of a previous common E-DCH resource instance. The first defined common E-DCH resource would occupy position 0 (or 1). The second defined common E-DCH resource would occupy position 1 (or 2). Similar reasoning would apply with the other defined resources.

A concrete realization would be, for instance, if the "Soffset" value for the first instance of the common E-DCH resource takes a default value and the rest of the common E-DCH resources take a value related to the last instance.

For example, a simple formula is presented below to set default values for each defined common E-DCH resource.

$$\text{Soffset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$$

where "offset" is the value of the last instance of the IE "Soffset". If the IE "Soffset" was not present in the first instance, "offset" is equal to zero.

"common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" may be zero (or one) for the first instance. If the IE is present, the signaled value overwrites the default value.

In some embodiments the position of the second available resource in the ordered list is defined by a default value in the Soffset information element, which default value is a function of the position of the second available resource within the ordered list, a function of a "Soffset" value of a previous first available resource, or a function of the position of the second available resource and an offset value. The offset value is an Soffset value of the first available resource.

#### >>>>F-DPCH Code Number

This IE indicates the code to be used for the F-DPCH. Instead of being MP, this IE is optional, conditional on value.

If the coding presented for the Soffset is applied, potentially, only three instances of the F-DPCH code number are needed, once for each 10 common E-DCH resources. Hence, in the best configuration, only three instances would need to be present.

Therefore, this IE is in various embodiments set as conditional on value (CV) so that this IE is mandatory present for the first occurrence. Alternatively, it should be mandatory present for the first occurrence or if the default value is equal to zero. Otherwise, this IE is optional. In addition, if this IE is not present, the value is equal to the last occurrence of this IE.

If the IE is present, the signaled value overwrites the default value. Thus, in some embodiments the F-DPCH code number information element may be the same for a maximum number of ten common E-DCH resources.

#### >>>>E-HICH Info

E-HICH info contains two additional IEs. Changes in this IE would imply impacts in Release 6 and Release 7 of the 3GPP standards. In order to avoid impacts in earlier versions, a new IE may be used instead: "E-HICH info for common E-DCH". Only two IEs would be needed as this feature only applies to FDD. In some embodiments the E-HICH info for common E-DCH information ele-

## 14

ment is defined by a channelization code and a signature sequence. A default value of the signature sequence may be a function of the position of the second available resource within the ordered list, a function of a "Signature Sequence" value of a previous first available resource, or a function of the position of the second available resource and the "Signature Sequence" value of a previous first available resource.

#### >>>>E-HICH Info for Common E-DCH

##### Channelisation Code

This IE may be set as a conditional on value (CV) IE so that the IE is mandatory only for the first instance and optional for the rest of them. If this IE is not present, the value is equal to the last occurrence of this IE. Thus, in some embodiments the channelization code of the second available resource may be equal to a channelization code of the first available resource. If the IE is present, the signaled value overwrites the default value.

##### Signature Sequence

The value of this IE is a number between 0 and 39. This IE in various embodiments is set as MD. If the IE is not present, "Signature sequence" takes a default value.

The default value is a function of the position of the common E-DCH resource within the list, a function the "Signature Sequence" value of a previous common E-DCH resource instance, or a function of the position of the common E-DCH resource and the "Signature Sequence" value of a previous common E-DCH resource instance. The first defined common E-DCH resource would occupy position 0 (or 1). The second defined common E-DCH resource would occupy position 1 (or 2). Similar reasoning would apply with the other defined resources. A concrete realization may be, for instance, if the "Signature sequence" for the first instance of the common E-DCH resource would take a default value and the rest of the common E-DCH resources would take a value function of the last instance of the IE.

For example, a simple formula is presented below to set default values for each defined common E-DCH resource in which the IE is not present.

$$\text{Signature Sequence} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 40$$

where "offset" is the value of the last occurrence of the IE "Signature Sequence". If

"Signature Sequence" was not present in the first instance, "offset" is equal to zero.

"common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero (or one) for the first instance.

If the IE is present, the signaled value overwrites the default value.

#### >>>>Uplink DPCH Code Info (for Common E-DCH)

##### Scrambling Code Number

Scrambling code number is a MP present value. This IE takes a relative large number of bits for each common E-DCH resource. This IE in some embodiments is changed to conditional on value (CV) instead, avoiding including such a large number of bits per configured common E-DCH resource.

Conditional on value would mean that this IE is mandatory present for the first occurrence. Otherwise, this IE is optional. In addition, if this IE is not present, the value is of the IE is a function of the last instance. For instance,

15

it could be a function of the position of the common E-DCH resource within the list of common E-DCH resources, a function of the “Uplink DPCCH code info for Common E-DCH” value of a previous common E-DCH resource instance, or a function of the position of the common E-DCH resource and the “Uplink DPCCH code info for Common E-DCH” value of a previous common E-DCH resource instance.

The following formula illustrates how the default values may be set if the IE is not included:

$$\text{Scrambling code number} = \text{offset} + \text{common E-DCH resource list position}$$

where “offset” is the value of the last occurrence of the IE “Scrambling code number”. If “offset” was not present in the first instance or occurrence, “offset” is equal to zero.

“common E-DCH resource list position” indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the “common E-DCH resource list position” is zero (or 1) for the first instance.

If the IE is present, the signaled value overwrites the default value.

Thus, in some embodiments the second available resource is defined by a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel. The value may be a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource or a function of the position of the second available resource and an “Uplink DPCCH code info for Common E-DCH” value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

16

>>E-DPDCH Info

E-DCH Minimum Set E-TFCI

This IE is mandatory default. If this IE is missing, it means that there is no minimum E-TFCI set.

In the case of E-DCH in CELL\_FACH and Idle Mode, the UE shall always send its message, especially CCCH messages. Otherwise, the UE will be blocked and, potentially, the UE will be dropped. It feels obvious that for E-DCH in CELL\_FACH and Idle Mode, the E-DCH minimum set E-TFCI will be always included and it necessary must be a number above zero (E-TFCI index 0 would only let the UE to send the Scheduling Information).

Therefore, the semantic description may be modified so that for CELL\_FACH and Idle Mode (or for Enhanced Uplink in CELL\_FACH and Idle Mode), if the IE is not included, the E-DCH minimum set E-TFCI is set to a defined value. The only restriction for this value is that the value belongs to the set of values defined in E-TFCI table. The concrete table to be used is indicated in the IE “E-TFCI table index” included also in the IE “E-DPDCH info”. As mentioned before, E-TFCI value zero only lets the UE to transmit the Scheduling Information. Therefore, the minimum reasonable E-TFCI value so that the UE can transmit user or higher layers control data is the E-TFCI value 1.

If the IE is present, the signaled values overwrite the default value.

Applying the encoding suggested before, the structure of the IE “PRACH preamble control parameters for Enhanced Uplink” and other IEs involved would result in shown below. Affected IEs are underlined and non-affected IEs are defined in reference to 3GPP Technical Specification (TS) 25.331 section 10 version 10.0.0: Common E-DCH system info IEs are illustrated in the table below

Condition	Explanation
Short	This IE is mandatory present for the first occurrence. Otherwise, this IE is optional.

Note1: These IEs correspond to the HS-DSCH configuration for CELL\_FACH, CELL\_PCH and URA\_PCH state on primary frequency, the configuration on secondary frequency is signalled to UE via dedicated signalling.

Note2: These IEs correspond to CCCH transmission configuration for CELL\_FACH state on the primary frequency and secondary frequency.

Note3: The default value is defined by:  $\text{Softset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$  where "offset" is the value of the last instance of the IE "Softset". If the IE "Softset" was not present in the first instance, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

## E-HICH Info for Common E-DCH

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
<u>ChannelisationCode</u>	<u>CV-Short</u>	<u>Integer</u> (0...127)	<u>If this IE is not present, the value is equal to the last occurrence of this IE.</u>	<u>REL-8</u>
<u>SignatureSequence</u>	<u>MD</u>	<u>Integer</u> (0...39)	<u>Note 1</u>	<u>REL-8</u>

Short This IE is mandatory present for the first occurrence.  
Otherwise, this IE is optional.

Note 1: The default value is defined by: Signature Sequence = (offset + common E-DCH resource list position) mod 40 where "offset" is the value of the last occurrence of the IE "Signature Sequence". If "Signature Sequence" was not present in the first occurrence, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

## Uplink DPCH Code Info for Common E-DCH

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
Scrambling code type	MP	Enumerated (short, long)		REL-8
<u>Scrambling codenumber</u>	<u>CV-Short</u>	<u>Integer</u> (0...16777215)	Note 1	REL-8
Condition	Explanation			
Short	This IE is mandatory present for the first occurrence. Otherwise, this IE is optional.			

Note 1: If this IE is not included, the value is given by: Scrambling code number = offset + common E-DCH resource list position where "offset" is the value of the last occurrence of the IE "scrambling code number". If the IE "scrambling code number" is not present in the first occurrence, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

The ASN.1 code would need to be updated as it follows  
(only relevant IEs have been added):

---

```

SysInfoType5 ::= SEQUENCE {
    sib6Indicator          BOOLEAN,

In some embodiments, a second approach may be taken to provide a backward compatible solution.

In this case a new IE is added in SIB5, “Common E-DCH System Info Short”, for instance. This IE would contain the new encoding. 35

The tabular of SIB5 would be as follows:

System Information Block type 5 and 5bis

Information Element/Group name	Need	Multi	Type and reference	Semantics description	Version
SIB6 Indicator	MP		Boolean	TRUE indicates that SIB6 is broadcast in the cell. When the UE receives SIB5 in the System Information Container message, this IE is interpreted as FALSE	
PhyCH information elements					
PICH Power offset	MP		PICH Power offset 10.3.6.50	If the cell is operating in MBSFN mode as indicated in subclause 8.1.1.6.3 the UE behaves as if this IE would not have been received.

Condition	Explanation
Optional	If the IE "Common E-DCH System Info" is present, the value of the IE is the same value of corresponding IE in the IE "Common E-DCH system info". Otherwise, this IE is optional.
Short	This IE is mandatory present for the first occurrence. Otherwise, this IE is optional.
Mandatory	If the IE "Common E-DCH System Info" is present, the value of the IE is the same value of the corresponding IE in the IE "Common E-DCH System Info". Otherwise, this IE is mandatory present.

Note 1: These IEs correspond to the HS-DSCH configuration for CELL\_FACH, CELL\_PCH and URA\_PCH state on primary frequency, the configuration on secondary frequency is signalled to UE via dedicated signalling.

Note 2: These IEs correspond to CCCH transmission configuration for CELL\_FACH state on the primary frequency and secondary frequency.

Note 3: The default value is defined by: Soffset = (offset + common E-DCH resource list position) mod 10 where "offset" is the value of the last instance of the IE "Soffset". If the IE "Soffset" was not present in the first instance, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

Additional conditions are placed in other to reduce the signalling in case the IE "Common E-DCH System Info" is included. The affected IEs are shown below:

PRACH Preamble Control Parameters (for Enhanced Uplink)

5

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
Available Signature	<u>MD</u>	Bit string(16)	The default value is the inverse bitstring indicated in the IE "Available Signature" in the IE "PRACH Info (for RACH)". Each bit indicates availability for a signature. Each available signature on the AICH is associated with one Common E-DCH Resource Configuration in the "Common E-DCH resource configuration information list".	<u>REL-8</u>
E-AI Indication	MP	BOOLEAN	TRUE: E-AIs are in use on the AICH. FALSE: E-AIs are not in use on the AICH.	REL-8
Preamble scrambling code number	<u>MD</u>	Integer (0 . . . 15)	The default value is the value indicated in the IE "Preamble scrambling code number" in the IE "PRACH Info (for RACH)". Identification of scrambling code, see [28]	<u>REL-8</u>
Available Sub Channel Number	<u>MD</u>	Bit string(12)	The default value is the same value indicated in the IE "Available Signatures" in the IE "PRACH system information list". Each bit indicates availability for a subchannel, where the subchannels are numbered "subchannel 0" to "subchannel 11". The value 1 of a bit indicates that the corresponding subchannel is available and the value 0 indicates that it is not available.	<u>REL-8</u>
PRACH partitioning	MD	PRACH partitioning 10.3.6.53	Default value is the value of "PRACH partitioning" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Persistence scaling factors	OP	Persistence scaling factors 10.3.6.48	This IE shall not be present if only ASC 0 and ASC 1 are defined. If this IE is absent, default value is the value of "Persistence scaling factors" in the first	REL-8

-continued

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
AC-to-ASC mapping	MD	AC-to-ASC mapping 10.3.6.1	occurrence in list "PRACH system information list" in SIB5 or SIB5bis, if value exists Default value is the value of "AC-to-ASC mapping" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Primary CPICH TX power	MD	Primary CPICH TX power 10.3.6.61	Default value is the value of "Primary CPICH TX power" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Constant value	MD	Constant value 10.3.6.11	Default value is the value of "Constant value" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
PRACH power offset	MD	PRACH power offset 10.3.6.54	Default value is the value of "PRACH power offset" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
PRACH transmission parameters	MD	RACH transmission parameters 10.3.6.67	Default value is the value of "RACH transmission parameters" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
AICH info	MD	AICH info 10.3.6.2	Default value is the value of "AICH info" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Power offset Pp-e	MP	Integer(-5 . . . 10)	In dB. Power offset between the last transmitted preamble and the initial DPCCH transmission as defined in [26]	REL-8

## E-HICH Info Common for E-DCH

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
<u>ChannelisationCode</u>	<u>CV-Short</u>	<u>Integer</u> <u>(0...127)</u>	<u>For the first occurrence, if this IE is not present, the value of this IE is the value of the last occurrence of the IE "Channelisation Code" present in the IE "Common E-DCH system info".</u> <u>For subsequent occurrences, if the IE is not</u>	<u>REL-8</u>

		<u>present the value</u> <u>is equal to the last</u> <u>occurrence of this</u> <u>IE.</u>		
<u>Signature Sequence</u>	<u>MD</u>	<u>Integer</u> <u>(0...39)</u>	<u>Note 1</u>	<u>REL-8</u>
Short	If the IE "Common E-DCH system info" is not present, this IE is mandatory present for the first occurrence. Otherwise, this IE is optional,			

Note 1: The default value is defined by: Signature Sequence = (offset + common E-DCH resource list position) mod 40 where "offset" is the value of last occurrence of the IE "Signature Sequence". If "Signature Sequence" was not present in the first instance, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

15

The IEs "E-DPCH info" and "Uplink DPCH code info for Common E-DCH" would not change compared with the first solution.

The encoding improvement of each IE present in "Common E-DCH System Info" are independent from other IEs.

Processing alternatively or additionally includes encoding system information that indicates available resources of a contention-based uplink channel relative to other available resources of that channel. In any case, processing finally includes broadcasting the system information to one or more mobile terminals 10.

Step 302. The base station 12 transmits the encoded system information to mobile terminals, e.g. the mobile terminal 10.

FIG. 4 is a block diagram depicting the base station 12 according to embodiments herein. To support the above downlink control signaling, the base station 12 in some embodiments includes one or more transmit/receive antennas 402, along with associated transmitter (TX) circuit 404 and receiver (RX) circuit 401, respectively, and further includes one or more processing circuits 403. The processing circuit 403 is configured to encode system information that directly indicates access request preambles for one of the CB channels and that indirectly indicates access request preambles for the other CB channel based on e.g. as a function of the directly indicated preambles. This may entail, for instance, suppressing encoding that would directly indicate certain access request preambles. The TX circuit 404 is then configured to broadcast the encoded system information to mobile terminals 10-10-N, via the transmit antennas 402.

In some embodiments, the processing circuit 403 of the base station 12 encodes system information that indicates available resources of a CB channel relative to other available resources of that channel, e.g., relative to a position in which other available resources are indicated in the system information, rather than indicating each resource independently. In some embodiments, for example, the available resources are indicated in an ordered list, and the processing circuit 403 encodes the system information to indicate available resources as a function of their position in the list relative to other resources. The TX circuit 404 then broadcasts this system information much in the same way as described above.

Thus, the base station 12 for managing access to the first contention based channel and the second contention based channel comprises the processing circuit 403. The processing circuit 403 is configured to encode system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the directly indicated first access request preambles. The base station 12 further comprises the trans-

mitter circuit 404 configured to broadcast the encoded system information to mobile terminals.

In some embodiments the first contention based channel may correspond to a random access channel, RACH, and in some embodiments, the second contention based channel corresponds to a common Enhanced Dedicated Channel, E-DCH. In some embodiments the second access request preambles may be derivable as a function of the first access request preambles. In some embodiments the encoded system information may be comprised in a System Information Block type 5, SIB5.

In some embodiments, the first access request preambles may correspond to Physical Random Access Channel, PRACH, preambles characterised by a signature sequence, a scrambling code, and a sub-channel. In some embodiments the first access request preambles may be indicated in an information element denoted as Physical Random Access Channel, PRACH, info comprised in a PRACH system information list carried in System Information Block type 5, SIB5. The first access request preambles for the first contention based channel may in some embodiments be indicated as available signatures in the information element PRACH info and the second access request preambles for the second contention based channel are indirectly indicated as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink. In some embodiments a preamble scrambling code number of the second access request preambles may be a preamble scrambling code of the first access request preambles. In some embodiments a preamble scrambling code number of the second access request preambles may be a function of the preamble scrambling code of the first access request preambles. In some embodiments the processing circuit 403 may be configured to set an available sub channel number of the second access request preambles to be equal, the inverse or a 'not'-function of an available sub channel number indicated in the information element denoted PRACH info.

In some embodiments the processing circuit 403 may further be configured to encode system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel. In some embodiments the second available resource may be indicated in an ordered list of resources as a function of a position of the first available resource in the ordered list. In some embodiments the ordered list may define common Enhanced-Dedicated Channel, E-DCH, resources, which each E-DCH Resource is defined by an Offset information element, a Fractional Dedicated Physical Control Channel, F-DPCH, code number informa-

60

65

tion element, and an E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel, E-HICH, info for common E-DCH information element. In some embodiments, the position of the second available resource in the ordered list may be defined by a default value in the Soffset information element. The default value may be a function of the position of the second available resource within the ordered list; a function of a "Soffset" value of a previous first available resource; or a function of the position of the second available resource and an offset value. The offset value may be an Soffset value of the first available resource. In some embodiments, the F-DPCH code number information element may be the same for a maximum of ten common E-DCH resources. In some embodiments the E-HICH info for common E-DCH information element may be defined by a channelization code and a signature sequence. A default value of the signature sequence may be a function of the position of the second available resource within the ordered list; a function of a "Signature Sequence" value of a previous first available resource; or a function of the position of the second available resource and the "Signature Sequence" value of a previous first available resource. In some embodiments a channelization code of the second available resource may be equal to a channelization code of the first available resource. In some embodiments the second available resource may be defined by a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel. The value may be a function of the position of the second available resource within the ordered list of common E-DCH resources; a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource; or a function of the position of the second available resource and an "Uplink DPCH code info for Common E-DCH" value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

Those skilled in the art will also appreciate that the various "circuits" described may refer to a combination of analog and digital circuits, and/or one or more processors configured with software and/or firmware, e.g., stored in memory, that, when executed by the one or more processors, perform as described above. One or more of these processors, as well as the other digital hardware, may be included in a single application-specific integrated circuit (ASIC), or several processors and various digital hardware may be distributed among several separate components, whether individually packaged or assembled into a system-on-a-chip (SoC).

FIG. 5 is a schematic flowchart depicting embodiments of a method in the mobile terminal 10 for requesting access to the wireless communication system. Those skilled in the art will further appreciate that a mobile terminal 10 herein is correspondingly configured to perform the method(s) illustrated in FIG. 5.

Step 501. The mobile terminal 10 receives broadcasted system information directly indicating first access request preambles for a first contention based channel, and indirectly indicating second access request preambles for a second contention based channel. The second access request preambles are indirectly indicated based on the directly indicated first access request preambles. Thus, processing at the mobile terminal 10 includes receiving system information that directly indicates the first access request preambles for the first contention-based uplink channel and indirectly indicates the second access request preambles for the second contention-based uplink channel.

Step 502. The mobile terminal 10 derives the second access request preambles from the first access request preambles. Thus, processing continues by deriving the access request preambles for the second contention-based uplink channel based on, e.g. as a function of, the directly indicated preambles.

Step 503. The mobile terminal 10 then requests access using the second access request preambles or the first access request preambles to access the wireless communication system. E.g. a selected second access request preamble may be transmitted to request access to the second contention-based uplink channel. Processing may further include randomly selecting one of the derived access request preambles. In some embodiments, the mobile terminal 10 randomly selects one of the access request preambles and transmits the randomly selected access request preamble.

The mobile terminal 10 may also be configured to generally perform processing, which may overlap the deriving of the access request preambles, that includes receiving system information that indicates a first available resource of the second contention-based uplink channel. Processing may optionally include in some embodiments randomly selecting an access request preamble corresponding to a second available resource of the second contention-based uplink channel, transmitting the selected preamble, and receiving a positive acknowledgement. Whether or not performed responsive to this optional step, processing comprises deriving system information for a second available resource of the second contention-based uplink channel based on, e.g. as a function of, the first available resource. Finally, processing in various embodiments concludes with transmitting uplink data on the second contention-based uplink channel using the second available resource. Thus, the mobile terminal 10 may randomly select one of the access request preambles and transmit the randomly selected access request preamble.

In some embodiments the first contention based channel corresponds to a random access channel, RACH. In some embodiments the second contention based channel corresponds to a common Enhanced Dedicated Channel, E-DCH. In some embodiments the received system information is comprised in a System Information Block type 5, SIB5.

In more detail, embodiments herein reduce the number of segments used in SIB5 to broadcast the IE "Common E-DCH System Info" which defines the common E-DCH resource parameters. For this purpose, a new coding is proposed for the IEs included in the IE "Common E-DCH System Info" within SIB5. The IE "Common E-DCH System Info" is an optional IE included in SIB5.

Embodiments herein propose modifications to these IEs, as detailed below. In some embodiments the first access request preambles correspond to Physical Random Access Channel, PRACH, preambles characterised by a signature sequence, a scrambling code, and a sub-channel.

>>PRACH Preamble Control Parameters for Enhanced Uplink

IE that comprises available signatures, Preamble scrambling code numbers, and Available Sub Channel Number  
Available Signatures

This is a bit string IE and each bit indicates whether a signature is used or not used. The signatures configured for RACH and included in the IE "Available Signatures" present in the IE "PRACH info (for RACH)". These signatures cannot be used for Enhanced Uplink in CELL\_FACH and Idle Mode. The IE "PRACH info (for RACH)" is included in the IE "PRACH System Information list" which is carried in SIB5. "PRACH System Information list", "PRACH info (for RACH)" and

47

“Available Signatures” are mandatory present IE. Hence, they will always be included in SIB5. Thus, in some embodiments the first access request preambles are indicated in an information element denoted as Physical Random Access Channel, PRACH, info comprised in a PRACH system information list carried in System Information Block type 5, SIB5.

The IE “Available Signatures” contained in the IE “PRACH preamble control parameters for Enhanced Uplink” is also a mandatory present value; however, in embodiments herein this IE is optional and takes a default value. This default value is the same or a function of another IE, e.g., the “Available Signatures” present in the IE “PRACH info (for RACH)”.

As an example, the default value in various embodiments is a “NOT” or “INVERSE” function operation of the bit string values included in “Available Signatures” present in the IE “PRACH info (for RACH)”.

An illustrative example is presented to clarify the concept. If the value of the IE “Available Signatures” included in the IE “PRACH info (for RACH)” is: 1111111100000000, then the default value of the IE “Available Signatures” contained in the IE “Common E-DCH System Info” would be the inverse bit operation of (1111111100000000) which is equal to 0000000011111111.

Therefore, the IE “available signatures” is set to mandatory default (MD) and the semantics of the description would say that the default value is the inverse bit-string indicated in the IE “Available Signature” in the IE “PRACH Info (for RACH)”. In other words, the available signatures for Enhanced Uplink in CELL\_FACH are those signatures which are not used for RACH, unless the IE is present. Doing so, the base station 12 suppresses including this IE in the IE “PRACH preamble control parameters for Enhanced Uplink” and thereby reduces downlink control signaling. The mobile terminal 10 that may not receive such an IE nevertheless sets the IE to a default value described above. If the IE is present, the signaled values overwrite the default value. Thus, in some embodiments the first access request preambles for the first contention based channel are indicated as available signatures in the information element PRACH info and the second access request preambles for the second contention based channel are indirectly indicated as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted

PRACH preamble control parameters for enhanced uplink. Preamble Scrambling Code Number

This IE is also included in the IE “PRACH info (for RACH)”. Embodiments herein teach that the scrambling code for the common E-DCH be the same as that of the RACH, at least by default. If it would be different, the new Preamble scrambling code number in various embodiments is a function of the Preamble scrambling code number present in the IE “PRACH info (for RACH)”. Hence, this IE in some embodiments is MD and by default equal to the IE “Preamble scrambling code number” indicated in the IE “PRACH info (for RACH),” and is otherwise a function of the IE “Preamble scrambling code number” indicated in the IE “PRACH info (for RACH)”.

As in the previous case, the base station 12 may refrain from including this IE in the IE “PRACH preamble control parameters for Enhanced Uplink” and thereby reduces downlink control signaling. A mobile terminal

48

10 that does not receive such an IE nevertheless sets the IE to a default value described above. If the IE is present, the signaled values overwrite the default value. Thus, in some embodiments a preamble scrambling code number of the second access request preambles is a preamble scrambling code of the first access request preambles. Alternatively, the preamble scrambling code number of the second access request preambles may be a function of the preamble scrambling code of the first access request preambles.

Available Sub Channel Number

This IE is a bit string. Each bit indicates availability for a subchannel, where the subchannels are numbered from “sub-channel 0” to “subchannel 11”. The value 1 of a bit indicates that the corresponding subchannel is available and the value 0 indicates that it is not available.

This IE is also included in the IE “PRACH info (for RACH)”. This IE in some embodiments is also set to MD. The mandatory default value is a function of the IE “PRACH info (for RACH)”.

For example, this IE may be set equal to the IE “Available Sub Channel Number” indicated in the IE “PRACH info (for RACH)”. In another approach, the default value may be the INVERSE (or NOT) function of the IE Available Sub Channel Number” indicated in the IE “PRACH info (for RACH)”

As in the previous case, the base station 12 may refrain from including this IE in the IE “PRACH preamble control parameters for Enhanced Uplink” and thereby reduces downlink control signaling. A mobile terminal 10 that does not receive such an IE nevertheless sets the IE to a default value described above. If the IE is present, the signaled values overwrite the default. Thus, in some embodiments an available sub channel number of the second access request preambles is set to be equal, the inverse or a ‘not’-function of an available sub channel number indicated in the information element denoted PRACH info.

In some embodiments, the base station 12 also reduces downlink control signaling by intelligently broadcasting system information that indicates available resources of a CB channel, e.g., the non-legacy CB channel.

Consider a specific example in 3GPP specifications, whereby available resources comprise a combination of a power control command channel time slot, a power control command channel coding, and the like, with each component of an available resource being indicated relative to a corresponding component of another available resource.

In some embodiments the mobile terminal 10 receives system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel. The second available resource may in some embodiments be indicated in an ordered list of resources as a function of a position of the first available resource in the ordered list.

The ordered list may in some embodiments define common Enhanced-Dedicated Channel (E-DCH) resources. Each E-DCH Resource may be defined by an Soffset information element, an Fractional Dedicated Physical Control Channel (F-DPCH) code number information element, and an E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel (E-HICH) info for common E-DCH information element.

>>Common E-DCH Resource Configuration Information List

This IE is a list which contains all the defined common E-DCH resources. A maximum of 32 common E-DCH

resources may be included in this list. For each defined common E-DCH resource, the following IEs are defined:

#### >>>>Soffset

This IE is a MP IE which value ranges between 0 and 9. This value indicates the concrete slot within the F-DPCH in which the power control commands are included for a concrete F-DPCH code.

Instead of being MP, this IE in various embodiments is set as MD. If the IE is not present, "Soffset" takes a default value. The default value is a function of the position of the common E-DCH resource within the list, a function the "Soffset" value of a previous common E-DCH resource instance, or a function of the position of the common E-DCH resource and the "Soffset" value of a previous common E-DCH resource instance. The first defined common E-DCH resource would occupy position 0 (or 1). The second defined common E-DCH resource would occupy position 1 (or 2). Similar reasoning would apply with the other defined resources.

A concrete realization would be, for instance, if the "Soffset" value for the first instance of the common E-DCH resource takes a default value and the rest of the common E-DCH resources take a value related to the last instance. For example, a simple formula is presented below to set default values for each defined common E-DCH resource.

$$\text{Soffset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$$

where "offset" is the value of the last instance of the IE "Soffset". If the IE "Soffset" was not present in the first instance, "offset" is equal to zero.

"common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" may be zero (or one) for the first instance.

If the IE is present, the signaled value overwrites the default value.

In some embodiments the position of the second available resource in the ordered list is defined by a default value in the Soffset information element, which default value is a function of the position of the second available resource within the ordered list, a function of a "Soffset" value of a previous first available resource, or a function of the position of the second available resource and an offset value. The offset value is an Soffset value of the first available resource.

#### >>>>F-DPCH Code Number

This IE indicates the code to be used for the F-DPCH.

Instead of being MP, this IE is optional, conditional on value.

If the coding presented for the Soffset is applied, potentially, only three instances of the F-DPCH code number are needed, once for each 10 common E-DCH resources. Hence, in the best configuration, only three instances would need to be present.

Therefore, this IE is in various embodiments set as conditional on value (CV) so that this IE is mandatory present for the first occurrence. Alternatively, it should be mandatory present for the first occurrence or if the default value is equal to zero. Otherwise, this IE is optional. In addition, if this IE is not present, the value is equal to the last occurrence of this IE.

If the IE is present, the signaled value overwrites the default value.

Thus, in some embodiments the F-DPCH code number information element may be the same for a maximum number of ten common E-DCH resources.

#### >>>>E-HICH Info

E-HICH info contains two additional IEs. Changes in this IE would imply impacts in Release 6 and Release 7 of the 3GPP standards. In order to avoid impacts in earlier versions, a new IE may be used instead: "E-HICH info for common E-DCH". Only two IEs would be needed as this feature only applies to FDD. In some embodiments the E-HICH info for common E-DCH information element is defined by a channelization code and a signature sequence. A default value of the signature sequence may be a function of the position of the second available resource within the ordered list, a function of a "Signature Sequence" value of a previous first available resource, or a function of the position of the second available resource and the "Signature Sequence" value of a previous first available resource.

#### >>>>E-HICH Info for Common E-DCH

##### Channelisation Code

This IE may be set as a conditional on value (CV) IE so that the IE is mandatory only for the first instance and optional for the rest of them. If this IE is not present, the value is equal to the last occurrence of this IE. Thus, in some embodiments the channelization code of the second available resource may be equal to a channelization code of the first available resource. If the IE is present, the signaled value overwrites the default value.

##### Signature Sequence

The value of this IE is a number between 0 and 39. This IE in various embodiments is set as MD. If the IE is not present, "Signature sequence" takes a default value.

The default value is a function of the position of the common E-DCH resource within the list, a function the "Signature Sequence" value of a previous common E-DCH resource instance, or a function of the position of the common E-DCH resource and the "Signature Sequence" value of a previous common E-DCH resource instance. The first defined common E-DCH resource would occupy position 0 (or 1). The second defined common E-DCH resource would occupy position 1 (or 2). Similar reasoning would apply with the other defined resources. A concrete realization may be, for instance, if the "Signature sequence" for the first instance of the common E-DCH resource would take a default value and the rest of the common E-DCH resources would take a value function of the last instance of the IE.

For example, a simple formula is presented below to set default values for each defined common E-DCH resource in which the IE is not present.

$$\text{Signature Sequence} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 40$$

where "offset" is the value of the last occurrence of the IE "Signature Sequence". If "Signature Sequence" was not present in the first instance, "offset" is equal to zero.

"common E-DCH resource list position" indicates the Common E-DCH resource

Configuration Information number by order of appearance.

The value of the "common E-DCH resource list position" is zero (or one) for the first instance. If the IE is present, the signaled value overwrites the default value.

## 51

>>>Uplink DPCH Code Info for Common E-DCH  
Scrambling Code Number

Scrambling code number is a MP present value. This IE takes a relative large number of bits for each common E-DCH resource. This IE in some embodiments is changed to conditional on value (CV) instead, avoiding including such a large number of bits per configured common E-DCH resource.

Conditional on value would mean that this IE is mandatory present for the first occurrence. Otherwise, this IE is optional. In addition, if this IE is not present, the value is of the IE is a function of the last instance. For instance, it may be a function of the position of the common E-DCH resource within the list of common E-DCH resources, a function of the “Uplink DPCH code info for Common E-DCH” value of a previous common E-DCH resource instance, or a function of the position of the common E-DCH resource and the “Uplink DPCH code info for Common E-DCH” value of a previous common E-DCH resource instance. The following formula illustrates how the default values may be set if the IE is not included:

$$\text{Scrambling code number} = \text{offset} + \text{common E-DCH resource list position}$$

where “offset” is the value of the last occurrence of the IE “Scrambling code number”. If “offset” was not present in the first instance or occurrence, “offset” is equal to zero.

“common E-DCH resource list position” indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the “common E-DCH resource list position” is zero (or 1) for the first instance. If the IE is present, the signaled value overwrites the default value.

Thus, in some embodiments the second available resource is defined by a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel. The value may be a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink

## 52

Dedicated Physical Control Channel of a previous first available resource or a function of the position of the second available resource and an “Uplink DPCH code info for Common E-DCH” value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

## &gt;&gt;E-DPDCH Info

## E-DCH Minimum Set E-TFCI

This IE is mandatory default. If this IE is missing, it means that there is no minimum E-TFCI set.

In the case of E-DCH in CELL\_FACH and Idle Mode, the UE shall always send its message, especially CCCH messages. Otherwise, the UE will be blocked and, potentially, the UE will be dropped. It feels obvious that for E-DCH in CELL\_FACH and Idle Mode, the E-DCH minimum set E-TFCI will be always included and it necessary must be a number above zero (E-TFCI index 0 would only let the UE to send the Scheduling Information).

Therefore, the semantic description may be modified so that for CELL\_FACH and Idle Mode (or for Enhanced Uplink in CELL\_FACH and Idle Mode), if the IE is not included, the E-DCH minimum set E-TFCI is set to a defined value. The only restriction for this value is that the value belongs to the set of values defined in E-TFCI table. The concrete table to be used is indicated in the IE “E-TFCI table index” included also in the IE “E-DPDCH info”. As mentioned before, E-TFCI value zero only lets the UE to transmit the Scheduling Information. Therefore, the minimum reasonable E-TFCI value so that the UE can transmit user or higher layers control data is the E-TFCI value 1.

If the IE is present, the signaled values overwrite the default value.

Applying the encoding suggested before, the structure of the IE “PRACH preamble control parameters for Enhanced Uplink” and other IEs involved would result in shown below. Affected IEs are underlined and non-affected IEs are defined in reference to 3GPP Technical Specification (TS) 25.331 section 10 version 10.0.0:

Condition	Explanation
Short	This IE is mandatory present for the first occurrence. Otherwise, this IE is optional.

Note1: These IEs correspond to the HS-DSCH configuration for CELL\_FACH, CELL\_PCH and URA\_PCH state on primary frequency, the configuration on secondary frequency is signalled to UE via dedicated signalling.

Note2: These IEs correspond to CCCH transmission configuration for CELL\_FACH state on the primary frequency and secondary frequency.

Note3: The default value is defined by:  $\text{Softset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$  where "offset" is the value of the last instance of the IE "Softset". If the IE "Softset" was not present in the first instance, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

### PRACH Preamble Control Parameters (for Enhanced Uplink)

## E-DPDCH Info

Information Element/Group name	Need	Multi	Type and reference	Semantics description	Version
E-TFCI table index	MP		Integer (0 . . . 1)	Indicates which standardised E-TFCI TB size table shall be used. See Note 3.	REL-6
<u>E-DCH minimum set E-TFCI</u>	<u>MD</u>		<u>Integer</u> <u>(0 . . . 127)</u>	<u>See [15];</u> <u>Absence means</u> <u>no E-DCH</u> <u>minimum set.</u> In CELL FACH and Idle Mode, the default value is 1.	<u>REL-6</u>
Reference E-TFCIs	MP	1 to 8		See [29]	REL-6
>Reference E-TFCI	MP		Integer (0 . . . 127)		REL-6
>Reference E-TFCI PO	MP		Integer (0 . . . 29,	Refer to quantization of the power offset in [28]	REL-6
			30, 31)	Values 30 and 31 are only used for E-TFCI > ETFCI Boost	REL-7
Minimum reduced E-DPDCH gain factor	OP		Enumerated (8/15, 11/15, 15/15, 21/15, 30/15, 42/15, 60/15, 84/15)	$\beta_{red, reduced, min}$ [29]; the default value is 8/15. If the configurable reduced E-DPDCH gain factor is not supported by the UE, the default value is used.	REL-8
Maximum channelisation codes	MP		Enumerated (sf256, sf128, sf64, sf32, sf16, sf8, sf4,		REL-6

-continued

Information Element/Group name	Need	Multi	Type and reference	Semantics description	Version
$PL_{non-max}$	MP		2sf4, 2sf2, 2sf2and2sf4) Real (0.44 . . . 1.0 by step of 0.04)	As defined in [27]	REL-6
Scheduling Information Configuration	MP				REL-6
>Periodicity for Scheduling Info - no grant	MD		Enumerated (everyEDCHT TI, 4, 10, 20, 50, 100, 200, 500, 1000)	Values in ms. Default value is "no report" NOTE 1.	REL-6
>Periodicity for Scheduling Info - grant	MD		Enumerated (everyEDCHT TI, 4, 10, 20, 50, 100, 200, 500, 1000)	Values in ms. Default value is "no report" NOTE 1.	REL-6
>Power Offset for Scheduling Info	MP		Integer (0 . . . 6)	Only used when no MACd PDUs are included in the same MACe PDU. Unit is in dB.	REL-6
3-Index-Step Threshold	MD		Integer (0 . . . 37)	Refers to an index in the "SG-Table" (see [15]). Default value is 0. NOTES 2, 3.	REL-6
2-Index-Step Threshold	MD		Integer (0 . . . 37)	Refers to an index in the "SG-Table" (see [15]). Default value is 0. NOTES 2, 3.	REL-6

NOTE 1: If the Periodicity is set to 4 ms and the E-DCH TTI is set to 10 ms, the UE shall interpret the periodicity value as 10 ms.

NOTE 2: If the 3-index-Step Threshold value is greater than 2-index-Step Threshold, the UE behaviour is unspecified.

NOTE 3: If the UE is operating in 16QAM mode, the value of "E-TFCI table index" is increased by 2, and indices in the SG-Table refer to Scheduling Grant Table 2 in [15].

## E-HICH Info for Common E-DCH

Information Element/Group name	Need	Multi	Type and reference	Semantics description	Version
<u>ChannelisationCode</u>	<u>CV-Short</u>		<u>Integer</u> (0...127)	<u>If this IE is not present, the value is equal to the last occurrence of this IE.</u>	<u>REL-8</u>
<u>SignatureSequence</u>	<u>MD</u>		<u>Integer</u> (0...39)	<u>Note 1</u>	<u>REL-8</u>

Short      This IE is mandatory present for the first occurrence.  
Otherwise, this IE is optional.

Note 1: The default value is defined by: Signature Sequence = (offset + common E-DCH resource list position) mod 40 where "offset" is the value of the last occurrence of the IE "Signature Sequence". If "Signature Sequence" was not present in the first occurrence, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

## Uplink DPCH code info for Common E-DCH

Information Element/Group name	Need	Multi	Type and reference	Semantics description	Version
Scrambling code type	MP		Enumerated (short, long)		REL-8
<u>Scramblingcodenumber</u>	<u>CV-Short</u>		<u>Integer</u> (0...16777215)	<u>Note 1</u>	<u>REL-8</u>

Condition	Explanation
Short	This IE is mandatory present for the first occurrence. Otherwise, this IE is optional.

The ASN.1 code would need to be updated as it follows  
(only relevant IEs have been added):

---

In some embodiments, a second approach may be taken to provide a backward compatible solution.

In this case a new IE needs to be added in SIB5, “Common 45 E-DCH System Info 60 Short”, for instance. This IE would contain the new encoding.

The tabular of SIB5 would be as follows:

System Information Block type 5 and 5bis

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
SIB6 Indicator	MP	Boolean	TRUE indicates that SIB6 is broadcast in the cell. When the UE receives SIB5 in the System Information Container message, this IE is interpreted as FALSE

Condition	Explanation
Optional	If the IE "Common E-DCH System Info" is present, the value of the IE is the same value of corresponding IE in the IE "Common E-DCH system info". Otherwise, this IE is optional.
Short	This IE is mandatory present for the first occurrence. Otherwise, this IE is optional.
Mandatory	If the IE "Common E-DCH System Info" is present, the value of the IE is the same value of the corresponding IE in the IE "Common E-DCH System Info". Otherwise, this IE is mandatory present.

NOTE 1: These IEs correspond to the HS-DSCH configuration for CELL\_FACH, CELL\_PCH and URA\_PCH state on primary frequency, the configuration on secondary frequency is signalled to UE via dedicated signalling.

NOTE 2: These IEs correspond to CCCH transmission configuration for CELL\_FACH state on the primary frequency and secondary frequency.

Note 3: The default value is defined by: Soffset = (offset + common E-DCH resource list position) mod 10 where "offset" is the value of the last instance of the IE "Soffset". If the IE "Soffset" was not present in the first instance, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

Additional conditions are placed in other to reduce the signalling in case the IE “Common E-DCH System Info” is included. The affected IEs are shown below:

PRACH Preamble Control Parameters (for Enhanced Uplink)

5

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
<u>AvailableSignature</u>	<u>MD</u>	<u>Bitstring(16)</u>	The default value is the inverse bit string indicated in the IE “AvailableSignature” in the IE “PRACH Info (for RACH)”. Each bit indicates availability for a signature. Each available signature on the AICH is associated with one Common E-DCH Resource Configuration in the “Common E-DCH resource configuration information list”.	<u>REL-8</u>
E-AI Indication	MP	BOOLEAN	TRUE: E-AIs are in use on the AICH. FALSE: E-AIs are not in use on the AICH.	REL-8
<u>Preamblescramblingcode number</u>	<u>MD</u>	<u>Integer(0...15)</u>	The default value is the value indicated in the IE “Preamble scrambling code number” in the IE “PRACH Info (for RACH)”. Identification of scrambling code, see [28]	<u>REL-8</u>
<u>AvailableSubChannelNumber</u>	<u>MD</u>	<u>Bitstring(12)</u>	The default value is the same value indicated in the IE “AvailableSignatures” in the IE “PRACH system information list”. Each bit indicates availability for a subchannel, where the subchannels are numbered “subchannel0” to “subchannel11”. The value 1 of a bit indicates that the corresponding subchannel is available and the value 0 indicates that it is not available.	<u>REL-8</u>
PRACH partitioning	MD	PRACH partitioning 10.3.6.53	Default value is the value of “PRACH partitioning” in the first occurrence in list “PRACH system information list” in SIB5 or SIB5bis.	REL-8
Persistence scaling factors	OP	Persistence scaling factors 10.3.6.48	This IE shall not be present if only ASC 0 and ASC 1 are defined. If this IE is absent, default value is the value of “Persistence scaling factors” in the first	REL-8

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
AC-to-ASC mapping	MD	AC-to-ASC mapping 10.3.6.1	occurrence in list "PRACH system information list" in SIB5 or SIB5bis, if value exists Default value is the value of "AC-to-ASC mapping" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Primary CPICH TX power	MD	Primary CPICH TX power 10.3.6.61	Default value is the value of "Primary CPICH TX power" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Constant value	MD	Constant value 10.3.6.11	Default value is the value of "Constant value" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
PRACH power offset	MD	PRACH power offset 10.3.6.54	Default value is the value of "PRACH power offset" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
PRACH transmission parameters	MD	RACH transmission parameters 10.3.6.67	Default value is the value of "RACH transmission parameters" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
AICH info	MD	AICH info 10.3.6.2	Default value is the value of "AICH info" in the first occurrence in list "PRACH system information list" in SIB5 or SIB5bis.	REL-8
Power offset Pp-e	MP	Integer(-5 . . . 10)	In dB. Power offset between the last transmitted preamble and the initial DPCH transmission as defined in [26]	REL-8

## E-HICH Info Common for E-DCH

Information Element/Group name	Need	Type and Multi reference	Semantics description	Version
<u>ChannelisationCode</u>	<u>CV-Short</u>	<u>Integer</u> <u>(0...127)</u>	<u>For the first occurrence, if this IE is not present, the value of this IE is the value of the last occurrence of the IE "Channelisation Code" present in the IE "Common E-DCH system info".</u> <u>For subsequent occurrences, if the IE is not</u>	<u>REL-8</u>

		<u>present the value</u> <u>is equal to the last</u> <u>occurrence of this</u> <u>IE.</u>		
<u>Signature Sequence</u>	<u>MD</u>	<u>Integer</u> <u>(0...39)</u>	<u>Note 1</u>	<u>REL-8</u>
Short	If the IE "Common E-DCH system info" is not present, this IE is mandatory present for the first occurrence. Otherwise, this IE is optional,			

Note 1: The default value is defined by: Signature Sequence = (offset + common E-DCH resource list position) mod 40 where "offset" is the value of last occurrence of the IE "Signature Sequence". If "Signature Sequence" was not present in the first instance, "offset" is equal to zero. "common E-DCH resource list position" indicates the Common E-DCH resource Configuration Information number by order of appearance. The value of the "common E-DCH resource list position" is zero for the first instance.

15

The IEs "E-DPCH info" and "Uplink DPCH code info for Common E-DCH" would not change compared with the first solution.

The encoding improvement of each IE present in "Common E-DCH System Info" are independent from other IEs.

FIG. 6 is a block diagram depicting embodiments of the mobile terminal 10. The mobile terminal 10 may include one or more transmit/receive antennas 601, along with associated transmitter (TX) circuit 602 and receiver (RX) circuit 603, respectively, and includes one or more processing circuits 604. The RX circuit 603 is configured to receive from the base station 12, via the receive antennas 601, broadcasted system information that directly indicates the access request preambles for one channel, e.g., the legacy CB channel such as a RACH. The processing circuit 604 is configured to then derive the access request preambles for the other channel, e.g., the non-legacy CB channel, such as a E-DCH, based on, e.g., as a function of, the directly indicated preambles. In some embodiments, the processing circuit 604 is further configured to randomly select from amongst the derived access request preambles, whereupon the TX circuit 602 is configured to transmit the selected preamble to the base station 12, in order to request access to the associated CB channel.

In some embodiment, the RX circuit 603 of the mobile terminal 10 is configured to receive system information that indicates a first available resource of a CB channel. The processing circuit 604 of the mobile terminal 10 may be configured to then derive information for a second available resource of the CB channel based on, e.g. as a function of, the first available resource. This may entail, for instance, deriving information for the second available resource according to a pre-determined rule that defines the second resource as a function of the first resource, e.g., as a function of the first resource's position within an ordered list describing the resources. The processing circuit 604 may optionally in some embodiments randomly select an access request preamble corresponding to a second available resource of the second contention-based uplink channel. The TX circuit 602 may then transmit selected preamble, and the RX circuit 603 may receive a positive acknowledgement. Whether or not performed responsive to the transmitted selected preamble, the processing circuit 604 may derive system information for a second available resource of the second contention-based uplink channel based on, e.g. as a function of, the first available resource. Finally, TX circuit 602 may in various embodiments conclude with transmitting uplink data on the second contention-based uplink channel using the second available resource.

Thus, embodiments of the mobile terminal 10 for requesting access to a wireless communication system are shown in FIG. 6. The mobile terminal 10 comprises the receiver circuit

603 configured to receive broadcasted system information directly indicating first access request preambles for the first contention based channel, and indirectly indicating second access request preambles for the second contention based channel based on the directly indicated first access request preambles. The mobile terminal 10 further comprises the processing circuit 604 configured to derive the second access request preambles from the first access request preambles, and configured to request access using the second access request preambles or the first access request preambles to access the wireless communication system. The processing circuit 604 may in some embodiments be further configured to randomly select one of the access request preambles and to transmit the randomly selected access request preamble.

The first contention based channel may correspond to a random access channel, RACH. The second contention based channel may correspond to a common Enhanced Dedicated Channel, E-DCH. The processing circuit 604 may in some embodiments be configured to derive the second access request preambles as a function of the first access request preambles. The received broadcasted system information may be comprised in a System Information Block type 5, SIB5. The first access request preambles may correspond to Physical Random Access Channel, PRACH, preambles characterised by a signature sequence, a scrambling code, and a sub-channel. In some embodiments the first access request preambles may be indicated in an information element denoted as Physical Random Access Channel, PRACH, info comprised in a PRACH system information list carried in System Information Block type 5, SIB5. In some embodiments the first access request preambles for the first contention based channel may be indicated as available signatures in the information element PRACH info and the second access request preambles for the second contention based channel may be indirectly indicated as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink. In some embodiments a preamble scrambling code number of the second access request preambles may be a preamble scrambling code of the first access request preambles. In some embodiments a preamble scrambling code number of the second access request preambles may be a function of the preamble scrambling code of the first access request preambles. In some embodiments an available sub channel number of the second access request preambles may be set to be equal, the inverse or a 'not-function' of an available sub channel number indicated in the information element denoted PRACH info.

In some embodiments the received broadcasted system information may further indicate the second available

65

81

resource of the second contention based channel relative to the first available resource of the second contention based channel. In some embodiments the second available resource may be indicated in an ordered list of resources as a function of a position of the first available resource in the ordered list. The ordered list may define common Enhanced-Dedicated Channel, E-DCH, resources, which each E-DCH Resource is defined by an Soffset information element, an Fractional Dedicated Physical Control Channel, F-DPCH, code number information element, and an E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel, E-HICH, info for common E-DCH information element. The position of the second available resource in the ordered list may be defined by a default value in the Soffset information element. The default value may be a function of the position of the second available resource within the ordered list, a function of a "Soffset" value of a previous first available resource, or a function of the position of the second available resource and an offset value. The offset value may be an Soffset value of the first available resource. In some embodiments the F-DPCH code number information element may be the same for a maximum of ten common E-DCH resources. In some embodiments the E-HICH info for common E-DCH information element may be defined by a channelization code and a signature sequence, and a default value of the signature sequence is a function of the position of the second available resource within the ordered list, a function of a "Signature Sequence" value of a previous first available resource, or a function of the position of the second available resource and the "Signature Sequence" value of a previous first available resource. In some embodiments a channelization code of the second available resource may be equal to a channelization code of the first available resource. In some embodiments the second available resource may be defined by a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel. The value may be a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource or a function of the position of the second available resource and an "Uplink DPCH code info for Common E-DCH" value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

Those skilled in the art will also appreciate that the various "circuits" described may refer to a combination of analog and digital circuits, and/or one or more processors configured with software and/or firmware (e.g., stored in memory) that, when executed by the one or more processors, perform as described above. One or more of these processors, as well as the other digital hardware, may be included in a single application-specific integrated circuit (ASIC), or several processors and various digital hardware may be distributed among several separate components, whether individually packaged or assembled into a system-on-a-chip (SoC).

In the drawings and specification, there have been disclosed exemplary embodiments. However, many variations and modifications can be made to these embodiments. Accordingly, although specific terms are employed, they are used in a generic and descriptive sense only and not for purposes of limitation, the scope of the embodiments herein being defined by the following claims.

The invention claimed is:

1. A method in a base station for managing access to a first contention based channel and a second contention based channel, the method comprising:

82

encoding system information, wherein the system information comprises:

system information that directly indicates first access request preambles for the first contention based channel, and indirectly indicates second access request preambles for the second contention based channel based on the directly indicated first access request preambles; and

system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel, wherein the second contention based channel is an Enhanced Dedicated Channel (E-DCH); and

broadcasting the encoded system information to mobile terminals;

wherein each E-DCH resource is defined by a Fractional Dedicated Physical Control Channel (F-DPCH) code number information element, an "E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel (E-HICH) info for common E-DCH" information element, and a Soffset information element that indicates a slot within the F-DPCH in which power control commands are included for the F-DPCH code number; and

the method further comprising instructing a mobile terminal to determine a default Soffset value for the second available resource as function of an Soffset value of the first available resource by omitting the Soffset information element for the second available resource in the encoded system information.

2. The method according to claim 1, wherein the first contention based channel is a random access channel (RACH).

3. The method according to claim 1, wherein said encoding comprises encoding the system information so that the second access request preambles are derivable as a function of the first access request preambles.

4. The method according to claim 1, wherein said encoding comprises encoding the system information to be included in a System Information Block type 5 (SIB5).

5. The method according to claim 1, wherein the first access request preambles correspond to Physical Random Access Channel (PRACH) preambles comprising a signature sequence, a scrambling code, and a sub-channel.

6. The method according to claim 5, wherein said encoding comprises encoding the system information to indirectly indicate a preamble scrambling code number of the second access request preambles as a preamble scrambling code of the first access request preambles.

7. The method according to claim 5, wherein said encoding comprises encoding the system information to indirectly indicate a preamble scrambling code number of the second access request preambles as a function of a preamble scrambling code of the first access request preambles.

8. The method according to claim 5, wherein said encoding comprises encoding the system information to indirectly indicate an available sub channel number of the second access request preambles as being equal to, or the inverse of, an available sub channel number indicated in an information element denoted PRACH info.

9. The method according to claim 1, wherein said encoding comprises encoding the system information to indicate the first access request preambles in an information element denoted as Physical Random Access Channel (PRACH) info included in a PRACH system information list carried in System Information Block type 5 (SIB5).

83

10. The method according to claim 9, wherein said encoding comprises encoding the system information to indicate the first access request preambles for the first contention based channel as available signatures in the information element PRACH info and to indirectly indicate the second access request preambles for the second contention based channel as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink.

11. The method according to claim 1, wherein the second available resource is indicated in an ordered list of resources as a function of the first available resource in the ordered list, and wherein said instructing the mobile terminal to determine a default Soffset value for the second available resource comprises causing the mobile terminal to determine the default Soffset value according to the following equation:

$$\text{Soffset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$$

where:

“offset” is the value of the Soffset information element in the encoded system information, and if the Soffset information is not present in the encoded system information then the offset is considered to be zero; and

“common E-DCH resource list position” indicates a position of the second available resource in the ordered list.

12. The method according to claim 11, wherein the position of the second available resource in the ordered list is defined by a default value in the Soffset information element, and wherein the default value is a function of the position of the second available resource within the ordered list, a function of a Soffset value of a previous first available resource, or a function of the position of the second available resource and an offset value that is an Soffset value of the first available resource.

13. The method according to claim 11, wherein the F-DPCH code number information element is the same for a maximum of ten common E-DCH resources.

14. The method according to claim 11, wherein the E-HICH info for common E-DCH information element is defined by a channelization code and a signature sequence, and wherein a default value of the signature sequence is a function of the position of the second available resource within the ordered list, a function of a “Signature Sequence” value of a previous first available resource, or a function of the position of the second available resource and the “Signature Sequence” value of a previous first available resource.

15. The method according to claim 14, wherein said encoding comprises encoding the system information to indicate a channelization code of the second available resource as being equal to a channelization code of the first available resource.

16. The method according to claim 11, wherein the second available resource is further defined by a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel, wherein that value is a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource, or a function of the position of the second available resource and an “Uplink DPCH code info for Common E-DCH” value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

17. A method in a mobile terminal for requesting access to a wireless communication system, the method comprising:

84

receiving broadcasted system information that comprises: system information that directly indicates first access request preambles for a first contention based channel, and indirectly indicates second access request preambles for a second contention based channel based on the directly indicated first access request preambles; and

system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel, wherein the second contention based channel is an Enhanced Dedicated Channel (E-DCH); and

deriving the second access request preambles from the first access request preambles and the second available resource; and

requesting access to the wireless communication system using the second access request preambles or the first access request preambles, and the second or the first available resource to access the second contention based channel or the first contention based channel, respectively, of the wireless communication system;

wherein each E-DCH resource is defined by a Fractional Dedicated Physical Control Channel (F-DPCH) code number information element, an “E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel (E-HICH) info for common E-DCH” information element, and a Soffset information element that indicates a slot within the F-DPCH in which power control commands are included for the F-DPCH code number; and

wherein if a Soffset information element is not received for the second available resource, the mobile terminal determines a default Soffset value for the second available resource as function of an Soffset value received for the first available resource.

18. The method according to claim 17, wherein said requesting comprises randomly selecting one of the access request preambles and transmitting the randomly selected access request preamble.

19. The method according to claim 17, wherein the first contention based channel is to a random access channel (RACH).

20. The method according to claim 17, wherein the second access request preambles are derivable as a function of the first access request preambles.

21. The method according to claim 17, wherein the received broadcasted system information is included in a System Information Block type 5 (SIB5).

22. The method according to claim 17, wherein the first access request preambles correspond to Physical Random Access Channel (PRACH) preambles comprising a signature sequence, a scrambling code, and a sub-channel.

23. The method according to claim 22, wherein said deriving comprises deriving a preamble scrambling code number of the second access request preambles as a preamble scrambling code of the first access request preambles.

24. The method according to claim 22, wherein said deriving comprises deriving a preamble scrambling code number of the second access request preambles as a function of a preamble scrambling code of the first access request preambles.

25. The method according to claim 22, wherein said deriving comprises deriving an available sub channel number of the second access request preambles as being equal to, or as being the inverse of, an available sub channel number indicated in an information element denoted PRACH info.

85

26. The method according to claim 17, wherein the first access request preambles are indicated in an information element denoted as Physical Random Access Channel (PRACH) info included in a PRACH system information list carried in System Information Block type 5 (SIB5).

27. The method according to claim 26, wherein the first access request preambles for the first contention based channel are indicated as available signatures in an information element PRACH info and wherein said deriving comprises deriving the second access request preambles for the second contention based channel as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink.

28. The method according to claim 17, wherein the second available resource is indicated in an ordered list of resources as a function of the first available resource in the ordered list, and wherein if a Soffset information element is not received for the second available resource, the mobile terminal determines the default Soffset value for the second available resource according to the following equation:

$$\text{Soffset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$$

where:

“offset” is the value of the Soffset information element in the broadcasted system information that indicates the first available resource, and if the Soffset information was not present in the broadcasted system information that indicates the first available resource then the offset is set to zero; and

“common E-DCH resource list position” indicates a position of the second available resource in the ordered list.

29. The method according to claim 28, wherein said deriving comprises deriving the position of the second available resource in the ordered list according to a default value in the Soffset information element, and wherein the default value is a function of the position of the second available resource within the ordered list, a function of a Soffset value of a previous first available resource, or a function of the position of the second available resource and an offset value that is an Soffset value of the first available resource.

30. The method according to claim 17, wherein the F-DPCH code number information element is the same for a maximum of ten common E-DCH resources.

31. The method according to claim 28, wherein the E-HICH info for common E-DCH information element is defined by a channelization code and a signature sequence, and wherein a default value of the signature sequence is a function of the position of the second available resource within the ordered list, a function of a “Signature Sequence” value of a previous first available resource, or a function of the position of the second available resource and the “Signature Sequence” value of a previous first available resource.

32. The method according to claim 31, wherein said deriving comprises deriving a channelization code of the second available resource as being equal to a channelization code of the first available resource.

33. The method according to claim 28, wherein said deriving comprises deriving the second available resource according to a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel, wherein that value is a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource or a function of

86

the position of the second available resource and an “Uplink DPCH code info for Common E-DCH” value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

34. A base station for managing access to a first contention based channel and a second contention based channel, the base station comprising:

a processing circuit configured to encode system information, wherein the system information comprises:

system information that directly indicates first access request preambles for the first contention based channel, and indirectly indicates second access request preambles for the second contention based channel based on the directly indicated first access request preambles; and

system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel, wherein the second contention based channel is an Enhanced Dedicated Channel (E-DCH); and

a transmitter circuit configured to broadcast the encoded system information to mobile terminals;

wherein each E-DCH resource is defined by a Fractional Dedicated Physical Control Channel (F-DPCH) code number information element, an “E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel (E-HICH) info for common E-DCH” information element, and a Soffset information element that indicates a slot within the F-DPCH in which power control commands are included for the F-DPCH code number; and

wherein the processing circuit is configured to instruct a mobile terminal to determine a default Soffset value for the second available resource as function of an Soffset value of the first available resource by omitting the Soffset information element for the second available resource in the encoded system information.

35. The base station according to claim 34, wherein the first contention based channel is a random access channel (RACH).

36. The base station according to claim 34, wherein the processing circuit is configured to encode the system information so that the second access request preambles are derivable as a function of the first access request preambles.

37. The base station according to claim 34, wherein the processing circuit is configured to encode the system information to be included in a System Information Block type 5 (SIB5).

38. The base station according to claim 34, wherein the first access request preambles correspond to Physical Random Access Channel (PRACH) preambles comprising a signature sequence, a scrambling code, and a sub-channel.

39. The base station according to claim 38, wherein the processing circuit is configured to encode the system information to indicate a preamble scrambling code number of the second access request preambles as a preamble scrambling code of the first access request preambles.

40. The base station according to claim 38, wherein the processing circuit is configured to encode the system information to indicate a preamble scrambling code number of the second access request preambles as a function of the preamble scrambling code of the first access request preambles.

41. The base station according to claim 38, wherein the processing circuit is configured to set an available sub channel number of the second access request preambles to be

equal to, or to be the inverse of, an available sub channel number indicated in an information element denoted PRACH info.

42. The base station according to claim 34, wherein the processing circuit is configured to encode the system information to indicate the first access request preambles in an information element denoted as Physical Random Access Channel (PRACH) info included in a PRACH system information list carried in System Information Block type 5 (SIB5).

43. The base station according to claim 42, wherein the processing circuit is configured to encode the system information to indicate the first access request preambles for the first contention based channel as available signatures in an information element PRACH info and to indirectly indicate the second access request preambles for the second contention based channel as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink.

44. The base station according to claim 34, wherein the second available resource is indicated in an ordered list of resources as a function of the first available resource in the ordered list, and wherein to instruct the mobile terminal to determine a default Soffset value for the second available resource, the processing circuit is configured to cause the mobile terminal to determine the default Soffset value according to the following equation:

$$\text{Soffset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$$

where:

“offset” is the value of the Soffset information element in the encoded system information, and if the Soffset information is not present in the encoded system information then the offset is considered to be zero; and

“common E-DCH resource list position” indicates a position of the second available resource in the ordered list.

45. The base station according to claim 44, wherein the position of the second available resource in the ordered list is defined by a default value in the Soffset information element, and wherein the default value is a function of the position of the second available resource within the ordered list, a function of a Soffset value of a previous first available resource, or a function of the position of the second available resource and an offset value that is an Soffset value of the first available resource.

46. The base station according to claim 44, wherein the F-DPCH code number information element is the same for a maximum of ten common E-DCH resources.

47. The base station according to claim 44, wherein the E-HICH info for common E-DCH information element is defined by a channelization code and a signature sequence, and wherein a default value of the signature sequence is a function of the position of the second available resource within the ordered list, a function of a “Signature Sequence” value of a previous first available resource, or a function of the position of the second available resource and the “Signature Sequence” value of a previous first available resource.

48. The base station according to claim 47, wherein the processing circuit is configured to encode the system information to indicate a channelization code of the second available resource as being equal to a channelization code of the first available resource.

49. The base station according to claim 44, wherein the second available resource is further defined by a value in an information element of a scrambling code of an uplink Dedi-

cated Physical Control Channel, wherein that value is a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource or a function of the position of the second available resource and an “Uplink DPCH code info for Common E-DCH” value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.

50. A mobile terminal for requesting access to a wireless communication system, the mobile terminal comprising:

a receiver circuit configured to receive broadcasted system information comprising:

system information that directly indicates first access request preambles for a first contention based channel, and indirectly indicates second access request preambles for a second contention based channel based on the directly indicated first access request preambles; and

system information that indicates a second available resource of the second contention based channel relative to a first available resource of the second contention based channel, wherein the second contention based channel is an Enhanced Dedicated Channel (E-DCH); and

a processing circuit configured to:

derive the second access request preambles from the first access request preambles and the second available resource; and

request access to the wireless communication system using the second access request preambles or the first access request preambles, and the second or the first available resource to access the second contention based channel or the first contention based channel, respectively, of the wireless communication system;

wherein each E-DCH resource is defined by a Fractional Dedicated Physical Control Channel (F-DPCH) code number information element, an “E-DCH Hybrid Automatic Repeat Request Acknowledgement Indicator Channel (E-HICH) info for common E-DCH” information element, and a Soffset information element that indicates a slot within the F-DPCH in which power control commands are included for the F-DPCH code number; and

wherein if a Soffset information element is not received for the second available resource, the mobile terminal determines a default Soffset value for the second available resource as function of an Soffset value received for the first available resource.

51. The mobile terminal according to claim 50, wherein the processing circuit is configured to request access to the wireless communication system by randomly selecting one of the access request preambles and transmitting the randomly selected access request preamble.

52. The mobile terminal according to claim 50, wherein the first contention based channel is a random access channel (RACH).

53. The mobile terminal according to claim 50, wherein the processing circuit is configured to derive the second access request preambles as a function of the first access request preambles.

54. The mobile terminal according to claim 50, wherein the received broadcasted system information is included in a System Information Block type 5 (SIB5).

55. The mobile terminal according to claim 50, wherein the first access request preambles correspond to Physical Ran-

89

dom Access Channel (PRACH) preambles comprising a signature sequence, a scrambling code, and a sub-channel.

56. The mobile terminal according to claim 55, wherein the processing circuit is configured to derive a preamble scrambling code number of the second access request preambles as a preamble scrambling code of the first access request preambles.

57. The mobile terminal according to claim 55, wherein the processing circuit is configured to derive a preamble scrambling code number of the second access request preambles as a function of the preamble scrambling code of the first access request preambles.

58. The mobile terminal according to claim 55, wherein the processing circuit is configured to derive an available sub channel number of the second access request preambles as being equal to, or as being the inverse of, an available sub channel number indicated in the information element denoted PRACH info.

59. The mobile terminal according to claim 50, wherein the first access request preambles are indicated in an information element denoted as Physical Random Access Channel (PRACH) info included in a PRACH system information list carried in System Information Block type 5 (SIB5).

60. The mobile terminal according to claim 59, wherein the first access request preambles for the first contention based channel are indicated as available signatures in the information element PRACH info and wherein the processing circuit is configured to derive the second access request preambles for the second contention based channel as a function of the first access request preambles in an information element denoted as available signatures in an information element denoted PRACH preamble control parameters for enhanced uplink.

61. The mobile terminal according to claim 50, wherein the second available resource is indicated in an ordered list of resources as a function of the first available resource in the ordered list, and wherein the processing circuit is configured to, if a Soffset information element is not received for the second available resource, determine the default Soffset value for the second available resource according to the following equation:

$$\text{Soffset} = (\text{offset} + \text{common E-DCH resource list position}) \bmod 10$$

where:

“offset” is the value of the Soffset information element in the broadcasted system information that indicates the

90

first available resource, and if the Soffset information is not present in the broadcasted system information that indicates the first available resource then the offset is set to zero; and

“common E-DCH resource list position” indicates a position of the second available resource in the ordered list.

62. The mobile terminal according to claim 61, wherein the processing circuit is configured to derive the position of the second available resource in the ordered list according to a default value in the Soffset information element, and wherein that default value is a function of the position of the second available resource within the ordered list, a function of a Soffset value of a previous first available resource, or a function of the position of the second available resource and an offset value that is an Soffset value of the first available resource.

63. The mobile terminal according to claim 61, wherein the F-DPCH code number information element is the same for a maximum of ten common E-DCH resources.

64. The mobile terminal according to claim 61, wherein the E-HICH info for common E-DCH information element is defined by a channelization code and a signature sequence, and wherein a default value of the signature sequence is a function of the position of the second available resource within the ordered list, a function of a “Signature Sequence” value of a previous first available resource, or a function of the position of the second available resource and the “Signature Sequence” value of a previous first available resource.

65. The mobile terminal according to claim 64, wherein the processing circuit is configured to derive a channelization code of the second available resource as being equal to a channelization code of the first available resource.

66. The mobile terminal according to claim 61, wherein the processing circuit is configured to derive the second available resource according to a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel, wherein that value is a function of the position of the second available resource within the ordered list of common E-DCH resources, a function of a value in an information element of a scrambling code of an uplink Dedicated Physical Control Channel of a previous first available resource or a function of the position of the second available resource and an “Uplink DPCH code info for Common E-DCH” value in the information element of a scrambling code of an uplink Dedicated Physical Control Channel of the previous first available resource.
